

Vertexing tridents

Sho Uemura

SLAC

Inputs

- Data: golden runs, pass3 (484551 nC, 77.51 nb^{-1})
 - ▶ pairs1 trigger, filtered on all SVT flags (bias, position, burst-mode noise, header)
- MC: tritrig-beam-tri, pass2, 4962 files (24.73 nb^{-1})
- Normalize to 7 PAC days luminosity (5420 nb^{-1})
- GBL tracks, unconstrained vertex Z
- Data-MC comparisons: black data, red MC

Cuts

- All cuts applied in `org.hps.analysis.dataquality.TridentMonitoring`
- Cuts copied from 2014 proposal:
 - ▶ Quality: track GBL $\chi^2 < 40$, beamspot-constrained vertex $\chi^2 < 5$
 - ▶ Beamspot-constrained vertex X and Y within 0.4 mm of origin
 - ▶ Track cuts: require top-bottom, $p(e^-), p(e^+) < 0.85$ GeV
 - ▶ Radiative cut: $p(V0) > 0.8 * E_{beam}$
 - ▶ Event cut: ≤ 5 tracks, exactly 1 positron track in event
 - ▶ Front layers: require L1 and L2 hits
 - ▶ L1 isolation: require > 0.5 mm to nearest strip
- No cluster information used

Vertex distributions

- I see the same data-MC differences Matt does (lower mass peak in MC, more low-energy tridents)

Vertex resolution

- Fit the Gaussian core of the vertex distribution, and exponential tail
- Good data-MC agreement

Radiative vertex sigma vs. mass

Vertex tails

- Count vertices outside of 3σ : tails are roughly 10^{-2} of total
- Tails asymmetric as expected
- Good data-MC agreement

Radiative vertex mass, +Z tail

Radiative vertex: Vertex Z vs. mass

Radiative vertex: Vertex Z vs. mass

Vertex Z-cut

- Z cut: $E(\text{events with } z > z_{\text{cut}}) = 0.5$
 - ▶ Blue curve on right is from proposal
- Fit vertex tail to exponential
- Normalize to 7 PAC days

Z cut for 0.5 background events

Radiative vertex Z, mass [0.0385, 0.0429] GeV

Z cut for 0.5 background events
